Reproducibility Notice

This project integrates the virtual environments framework provided by the `renv` package for computational reproducibility. By taking this approach, all results are generated using a consistent versioning of both R and several R packages. This version of the report was built with R version 4.0.4 (2021-02-15), `pandoc` version 2.2, and the following R packages:

This table summarizes characteristics of per-protocol participants in the immunogenicity subcohort, which was randomly sampled from the study cohort. The sampling was stratified by strata defined by enrollment characteristics: Assigned randomization arm × Baseline SARS-CoV-2 seronegative vs. seropositive × Randomization strata. The U.S. subcohort includes 8 baseline demographic strata; the Latin America and South Africa subcohorts each include 4 baseline demographic strata.

This table summarizes characteristics of per-protocol participants in the immunogenicity subcohort, which was randomly sampled from the study cohort. The sampling was stratified by strata defined by enrollment characteristics: Assigned randomization arm × Baseline SARS-CoV-2 seronegative vs. seropositive × Randomization strata. The U.S. subcohort includes 8 baseline demographic strata; the Latin America and South Africa subcohorts each include 4 baseline demographic strata.

Cases for Day 29 markers are baseline negative per-protocol vaccine recipients with the symptomatic infection COVID-19 primary endpoint diagnosed starting 7 days after the Day 29 study visit. Non-cases/Controls are baseline negative per-protocol vaccine recipients sampled into the random subcohort with no COVID-19 endpoint diagnosis by the time of data-cut.

N is the number of cases sampled into the subcohort within baseline covariate strata.

The denominator in Resp Rate is the number of participants in the whole per-protocol cohort within baseline covariate strata, calculated using inverse probability weighting.

Day D29 Univariate CoR: Cox Models of Risk

The main regression model is the Cox proportional hazards model. All plots are made with Cox models fit unless specified otherwise.

3.1 Hazard ratios

Table 3.1.1: Inference for Day 29 antibody marker covariate-adjusted correlates of risk of COVID in the vaccine group: Hazard ratios per 10-fold increment in the marker*

MockENSEMBLE Immunologic Marker	No. cases / No. at-risk**	HR per 10-fold incr. Pt. Est.	95% CI	P-value (2-sided)	q-value ***	FWER
Anti Spike IgG (BAU/ml)	167/19,203	0.41	(0.31-0.54)	<0.001	<0.001	<0.001
Anti RBD IgG (BAU/ml)	167/19,203	0.52	(0.40-0.67)	<0.001	<0.001	<0.001

*Baseline covariates adjusted for: baseline risk score, region (US, South Africa, or Latin American). Maximum failure event time 149 days.

**No. at-risk = estimated number in the population for analysis: baseline negative per-protocol vaccine recipients not experiencing the COVID endpoint through 6 days post Day 29 visit; no. cases = number of this cohort with an observed COVID endpoint.

***q-value and FWER (family-wide error rate) are computed over the set of p-values both for quantitative markers and categorical markers using the Westfall and Young permutation method (10 replicates).

† Count cases starting 7 days post Day 29.

Table 3.1.2: Inference for Day 29 antibody marker covariate-adjusted correlates of risk of COVID in the vaccine group: Hazard ratios for Middle vs. Upper tertile vs. Lower tertile*

Placebo		513/19,233	0.0267						

*Baseline covariates adjusted for: baseline risk score, meeting the protocol randomization stratification criterion for being at heightened risk of COVID (yes or no), strata(Region). Maximum failure event time 149 days. Cutpoints: Anti Spike IgG (BAU/ml) [0.73, 1.25], Anti RBD IgG (BAU/ml) [0.94, 1.54], all on the log10 scale.

**No. at-risk = estimated number in the population for analysis: baseline negative per-protocol vaccine recipients not experiencing the COVID endpoint through 6 days post Day 29 visit; no. cases = number of this cohort with an observed COVID endpoint.

***Generalized Wald-test p-value of the null hypothesis that the hazard rate is constant across the Lower, Middle, and Upper tertile groups.

† q-value and FWER (family-wide error rate) are computed over the set of p-values both for quantitative markers and categorical markers using the Westfall and Young permutation method (10 replicates).

3.2 Marginalized risk and controlled vaccine efficacy plots

Table 3.2.1: Analysis of Day 29 markers (upper vs. lower tertile) as a CoR and a controlled risk CoP.

	marginalized risk		controlled risk		$e(0,1)^2$	
	ratio $RR_M(0, 1)$	Point Est. 95% CI	ratio $RR_C(0, 1)^1$	Point Est. 95% CI	Point Est. 95% CI UL

Anti RBD IgG (BAU/ml)	0.36	0.24–0.60	0.48	0.32–0.81	4.9	2.7

¹Conservative (upper bound) estimate assuming unmeasured confounding at level $RR_{UD}(0, 1) = RR_{EU}(0, 1) = 2$ and thus $B(0, 1) = 4/3$.

²E-values are computed for upper tertile ($s = 1$) vs. lower tertile ($s = 0$) biomarker subgroups after controlling for baseline risk score, meeting the protocol randomization stratification criterion for being at heightened risk of COVID (yes or no), strata(Region); UL = upper limit.

Table 3.2.3: Controlled VE as functions of Day 29 markers (=s) among baseline negative vaccine recipients with 95% bootstrap point-wise confidence intervals (10 replicates). Overall cumulative incidence from 7 to 149 days post Day 29 was 0.009 in vaccine recipients compared to 0.027 in placebo recipients, with cumulative vaccine efficacy 67.4% (95% CI 64.4 to 71.5%).

Day D29start1 Univariate CoR: Cox Models of Risk

The main regression model is the Cox proportional hazards model. All plots are made with Cox models fit unless specified otherwise.

*Baseline covariates adjusted for: baseline risk score, region (US, South Africa, or Latin American). Maximum failure event time 149 days.

**No. at-risk = estimated number in the population for analysis: baseline negative per-protocol vaccine recipients not experiencing the COVID endpoint through Day 29 visit; no. cases = number of this cohort with an observed COVID endpoint.

***q-value and FWER (family-wide error rate) are computed over the set of p-values both for quantitative markers and categorical markers using the Westfall and Young permutation method (10 replicates).

Maximum failure event time 149 days. Cutpoints: Anti Spike IgG (BAU/ml) [0.73, 1.25], Anti RBD IgG (BAU/ml) [0.94, 1.54], all on the log10 scale.

Average follow-up of vaccine recipients (in the D29start1 correlates analyses population) starting at 7 days post Day 29 visit (not counting the 7 days) is 154 days.

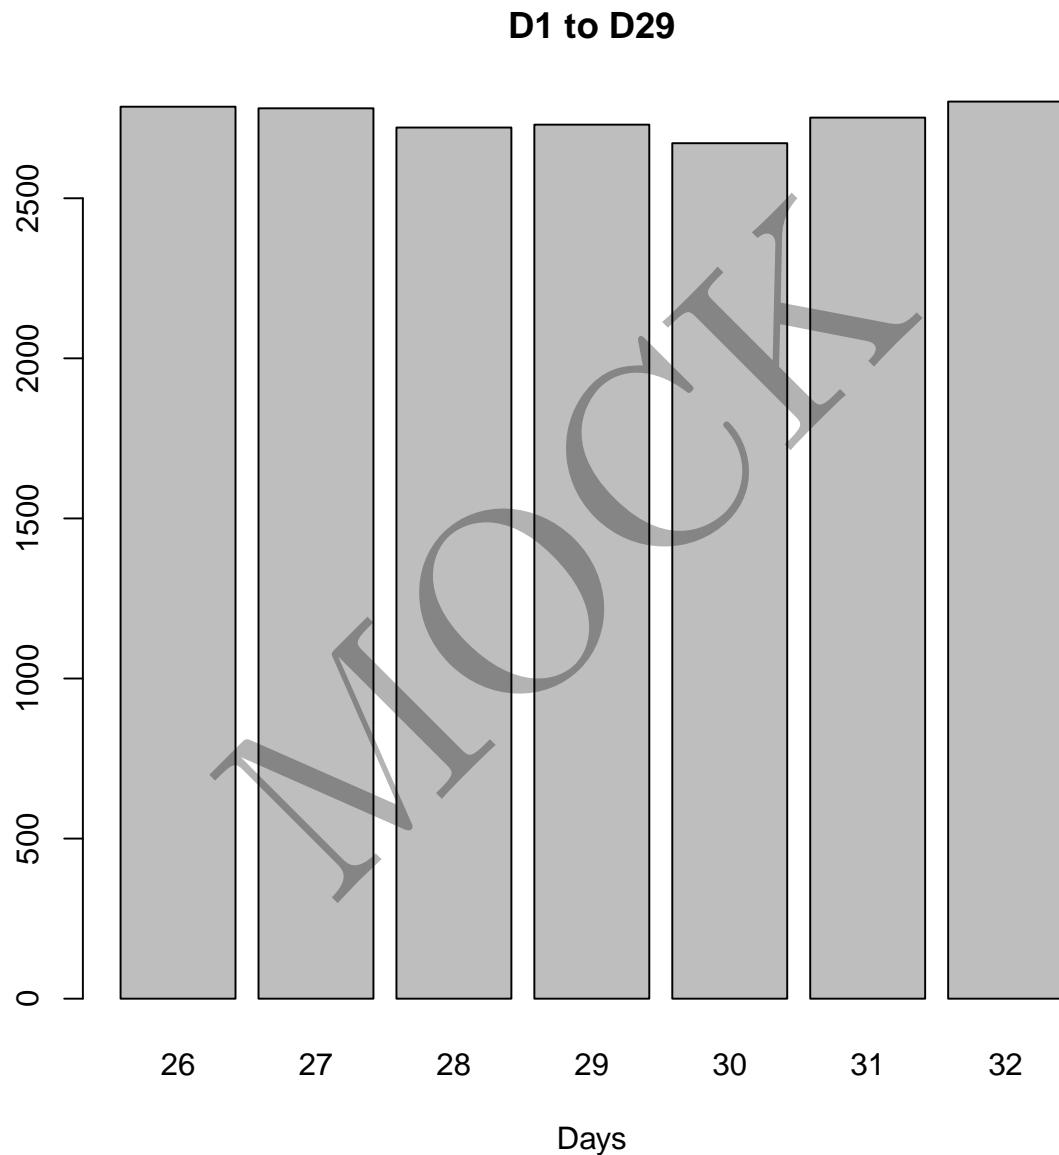

Figure 4.3.1: Distribution of the number of days between visits in the per-protocol immunogenicity subcohort, vaccine arm, baseline negative. The median (IQR) number of days between Day 1 and Day 29 was 29 (27-31). ‡ Count cases starting 1 days post Day 29.

Chapter 5

Univariate CoR: Nonparametric Threshold Modeling ($>= s$)

An extension of the unadjusted nonparametric threshold-searching approach developed in Donovan, Hudgens, and Gilbert (2019), the covariate-adjusted TMLE-based approach developed by van der Laan, Zhang, Gilbert (submitted) is used to estimate the so-called threshold-response function $E_X[E[Y | S \geq s, X, A = 1] | A = 1]$ for a range of thresholds s . Here, X is a set of baseline characteristics, $A = 1$ represents the vaccine group, S is the biomarker/immune-response/correlate of interest, and Y is the indicator of COVID disease before some time point t_f . This parameter can be viewed as a causal/covariate-adjusted version of the parameter $P(Y = 1 | S \geq s, A = 1)$. Intuitively, the threshold-response at a given threshold is the expected probability of obtaining COVID disease if one experiences a marker/immune-response value above that threshold. The threshold-response function is estimated for each of the four Day 57 antibody markers, in each case adjusting for the baseline covariates: baseline risk score, high risk indicator, and underrepresented minority status. A restrictive but flexible specification of the Highly Adaptive Lasso estimator is used for the covariate adjustment. A number of plots and tables are reported:

1. A plot and table with risk estimates and point-wise 95% confidence intervals
2. A plot and table with risk estimates and simultaneous 95% confidence bands
3. Monotone-corrected versions of 1 and 2.

A reverse cumulative distribution function curve estimated by the IPW NPMLE of the marker values is superimposed on the threshold-response plots and a dashed red line is added to mark the threshold value after which no more events are observed.

The blue dots on the plots represent the risk predictions at marker values where there was an observed COVID-19 case.

Day D29 Univariate CoR: Nonlinear modeling

To explore nonlinear association and threshold modeling, we fit smoothing spline models with degrees of freedom selected by cross-validation using the mgcv R package.

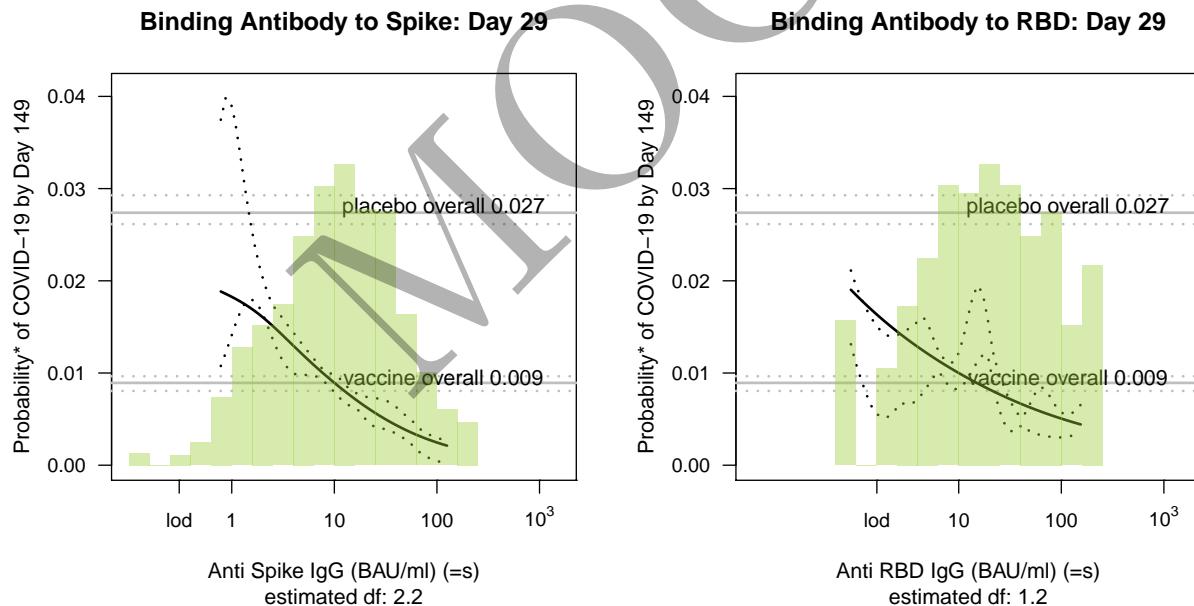

Figure 7.0.1: Marginalized risk as functions of Day 29 markers (=s) among baseline seronegative vaccine recipients with 95% bootstrap point-wise confidence bands (5 replicates) as modeled by GAM with automatic smoothness estimation. Baseline covariates adjusted for: baseline risk score, Region (US, South Africa, Latin America). The horizontal lines indicate the overall cumulative risk of the vaccine and placebo arms by Day 149 and its 95% point-wise confidence interval. Histograms of the immunological markers in the vaccine arm are overlaid. lod = 0.3, 1.6, 2.4, 15 for bAb Spike, bAb RBD, PsV nAb ID50, PsV nAb ID80, respectively. ‡ Count cases starting 7 days post Day 29.
